Dear Sir:

This is in response to Office action summery of 02/10/2006.

Applicant elects for examination Figure 12.

We transverse the decision. The prior art shows a number of devices that emit a certain amount of cleaner with each flush. Since the water drops rapidly with each flush, the response of the siphon must be delayed. As part of our inventive process we determined the fluid exit form the siphon must be delayed. The embodiments shown in Figures 10 through 16 are obvious variants on this species.

The obvious embodiments shown in Figure 10 through 16 do not exist in a vacuum. They act to delay the exit of the water within the siphon of the device to aliquot cleanser.

Figures 1-5 are variant embodiments. The elements are the same except the are in different arrangements. These elements are: a cleanser reservoir, a pin hole, a catchment (aliquoting) volume, an air source opening to allow ambient air in, and siphon with an restricted exit. The siphon removes the cleanser from the reservoir. Figure 4 has a replaceable reservoir.

In fact, all embodiments are obvious variation on this theme. All reservoirs as in Figures through 9 and 16 through 18 have these elements.
